ESTYMACJA WSPÓŁCZYNNIKA AUTOKORELACJI W SZEREGU CZASOWYM AR(1)

XXXIX Ogólnopolska Konferencja Zastosowań Matematyki
Zakopane-Kościelisko 7 - 14 września 2010 r.

$$X_t = \rho X_{t-1} + \varepsilon_t, \quad t = \dots, -1, 0, 1, \dots, \quad |\rho| < 1$$

$$X_t = \rho X_{t-1} + \varepsilon_t, \quad t = \dots, -1, 0, 1, \dots, \quad |\rho| < 1$$

$$\varepsilon_t, \quad t = \dots, -1, 0, 1, \dots, \quad i.i.d. \quad N(0, \sigma),$$

$$X_t = \rho X_{t-1} + \varepsilon_t, \quad t = \dots, -1, 0, 1, \dots, \quad |\rho| < 1$$

$$\varepsilon_t, \quad t = \dots, -1, 0, 1, \dots, \quad i.i.d. \quad N(0, \sigma), \quad \sigma = 1$$

$$X_t = \rho X_{t-1} + \varepsilon_t, \quad t = \dots, -1, 0, 1, \dots, \quad |\rho| < 1$$

$$\varepsilon_t, \quad t = \dots, -1, 0, 1, \dots, \quad i.i.d. \quad N(0, \sigma), \quad \sigma = 1$$

Obserwacja

$$X_T, X_{T+1}, \dots, X_{T+n-1},$$

$$X_t = \rho X_{t-1} + \varepsilon_t, \quad t = \dots, -1, 0, 1, \dots, \quad |\rho| < 1$$

$$\varepsilon_t, \quad t = \dots, -1, 0, 1, \dots, \quad i.i.d. \quad N(0, \sigma), \quad \sigma = 1$$

Obserwacja

$$X_T, X_{T+1}, \dots, X_{T+n-1}, \quad T = 1$$

Maximum Likelihood Estimator:

$$\hat{\rho}_{MLE} = \arg \max_{\rho} \mathcal{L}(\rho; X_1, X_2, \dots, X_n)$$

where

$$\mathcal{L}(\rho; x_1, x_2, \dots, x_n) = \log(1 - \rho^2) - x_1^2(1 - \rho^2) - \sum_{i=2}^n (x_i - \rho x_{i-1})^2.$$

Observe that for every x_1, x_2, \dots, x_n , function $\mathcal{L}(\rho; x_1, x_2, \dots, x_n)$, $\rho \in (-1, 1)$ is concave (second derivative is negative), $\mathcal{L}(\rho; x_1, x_2, \dots, x_n) \rightarrow -\infty$ as $\rho \rightarrow \pm 1$ so that $\hat{\rho}_{MLE} \in (-1, 1)$ is uniquely defined. A disadvantage of the estimator is that no simple explicit formula for computing $\hat{\rho}_{MLE}$ is known.

Least Square Estimator:

$$\hat{\rho}_{LSE} = \arg \min_{\rho} \sum_{i=2}^n (X_i - \rho X_{i-1})^2 = \frac{\sum_{i=2}^n X_i X_{i-1}}{\sum_{i=2}^n X_{i-1}^2}$$

Hurwicz estimator

$$\rho_{HUR} = \text{Med} \left(\frac{X_2}{X_1}, \frac{X_3}{X_2}, \dots, \frac{X_n}{X_{n-1}} \right)$$

where $\text{Med}(\xi_1, \xi_2, \dots, \xi_m)$ denotes a median of $\xi_1, \xi_2, \dots, \xi_m$.
A nice property of the estimator is that it is median-unbiased
which means that

$$P_\rho\{\hat{\rho}_{HUR} \leq \rho\} = P_\rho\{\hat{\rho}_{HUR} \geq \rho\} = \frac{1}{2}, \quad \text{for all } \rho \in (-1, 1).$$

Haddad estimator:

$$\rho_{HAD} = \frac{\text{Med}(X_{t-1}X_t)}{\text{Med}(X_t^2)}$$

The estimator has been constructed as a robust counterpart of the least square estimator.

M-estimator with Huber loss function: 13

$$\rho_{MHU} = \arg \min_{\rho} \sum_{i=1}^{n-1} L(X_{i+1} - \rho X_i)$$

with

$$L(x) = \begin{cases} \frac{1}{2}x^2 & \text{if } |x| \leq k, \\ k|x| - \frac{1}{2}k^2 & \text{if } |x| > k \end{cases}$$

Following Lehmann we assume $k = 3/2$

No simple explicit formula for computing $\hat{\rho}_{MHU}$ is known

Burg's estimator:

The estimator has been constructed as that minimizing the forward and backward prediction errors:

$$\rho_{BUR} = \arg \min_{\rho} \sum_{i=2}^n ((X_i - \rho X_{i-1})^2 + (X_{i-1} - \rho X_i)^2)$$

Then

$$\rho_{BUR} = \frac{2 \sum_{i=2}^n X_i X_{i-1}}{\sum_{i=2}^n (X_i^2 + X_{i-1}^2)}$$

It should be noted that the support of the estimator ρ_{BUR} is in the interval $(-1, 1)$

ENTROPY LOSS FUNCTION

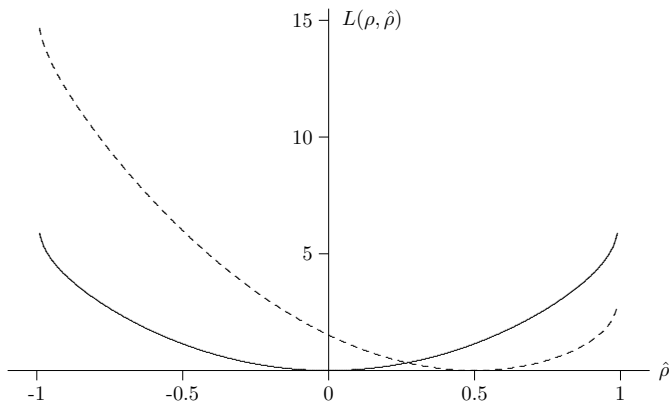

Fig.1. Entropy Loss Functions for $\rho = 0$ (solid) and $\rho = 0.5$ (dashed)

$$L(\theta, \hat{\theta}) = E_{\theta} \log \left(\frac{f_{\theta}(X)}{f_{\hat{\theta}}(X)} \right)$$

$$L(\rho, \hat{\rho}) = \begin{cases} \frac{1}{2} \log \frac{1-\rho^2}{1-\hat{\rho}^2} + \frac{\rho-\hat{\rho}}{2(1-\rho^2)} \left(n\rho - (n-2)\hat{\rho} \right), & \text{if } |\hat{\rho}| < 1, \\ +\infty, & \text{if } |\hat{\rho}| \geq 1. \end{cases}$$
